(57) **ABSTRACT**

Methods and systems directed to dispensing fluids, such as beverages, using wireless technology are provided. Aspects relate to a container, such as a beverage cup, having a wireless transceiver configured to transmit and/or receive wireless signals to a second wireless transceiver associated with a dispenser. The wireless transceiver may be configured to transmit electronic signals indicative that the container is validated to receive a beverage and whether it is properly located to receive the beverage from a valve of the dispenser. Further aspects of the invention relate to a beverage dispensing system having a wireless transceiver. In one embodiment, the dispenser is configured to receive a return signal from a container indicative that the container is validated to receive a beverage and whether the container is properly located to receive a beverage from a valve of the dispenser.

BEVERAGE DISPENSE VALVE CONTROLLED BY WIRELESS TECHNOLOGY

RELATED APPLICATION

The present application is a continuation of U.S. patent application Ser. No. 12/704,217, filed on Feb. 11, 2010, which claims the benefit of U.S. Provisional Patent Application No. 61/151,770, filed on Feb. 11, 2009, which are incorporated by reference herein and made a part hereof.

FIELD OF THE INVENTION

The invention relates generally to dispensing fluids. More specifically, the invention provides methods and systems for dispensing fluids, such as beverages, using wireless technology.

BACKGROUND OF THE INVENTION

The present invention relates to dispensing fluids, such as beverages, using wireless technology. Retail establishments, for example fast food restaurants and convenience stores, often utilize fountain drink dispensers to dispense servings of different beverages to multiple users. Using such beverage dispensers allows consumers to purchase a cup or other containers that may be filled with one or more beverages at the beverage dispenser. Unfortunately, however, traditional systems cannot adequately monitor the user's actions to confirm the user obtained the beverage paid for. Indeed, some "premium" beverages may be offered at the beverage dispenser, however, there is no efficient method or system to efficiently monitor whether consumers pay for the drink they consume.

SUMMARY OF THE INVENTION

The following presents a simplified summary of the disclosure in order to provide a basic understanding of some aspects of the invention by way of exemplary embodiments. These embodiments do not define key or critical elements of the invention or to delineate the scope of the invention. The following summary merely presents some of the concepts of the disclosure in a simplified form as a prelude to the more detailed description of aspects of the invention provided below.

Aspects of the invention relate to a beverage dispensing system, having at least one beverage container and at least one beverage dispenser. The beverage container may include a sidewall disposed around a central bottom, wherein the bottom is distal to an opening for receiving a beverage, and a container wireless transceiver associated with the container. In one embodiment, the container wireless transceiver may be affixed to the bottom of the container. In other embodiments, the container wireless transceiver may be affixed to the sidewall of the container. Yet in other embodiments, the container wireless transceiver may be located in an impermeable layer between the sidewall and the bottom of the container, wherein the impermeable layer is not in fluid communication with the location where the beverage would be received in the opening. Additionally, the container wireless transceiver may be configured to transmit an electronic signal indicative that the beverage container is validated to receive a beverage and whether the beverage container is properly located to receive the beverage from the valve of the drink dispenser.

In aspects in accordance with this invention, the beverage dispenser may include a housing, a valve extending from the

2

housing configured to dispense the beverage into the container located below the valve, and a dispenser wireless transceiver located in close proximity to the beverage dispenser configured to communicate with the container wireless transceiver on the beverage container. The beverage dispenser may further include a valve lever that extends from the housing, wherein in some embodiments the dispenser wireless transceiver may be located on the valve lever. In other embodiments, the valve lever may include a lever backing that extends from the housing, wherein the dispenser wireless transceiver is located on the lever backing. The dispenser wireless transceiver may be configured to receive a return signal from a compatible container indicative that the beverage container is validated to receive the beverage from the beverage dispenser and whether the beverage container is properly located to receive the beverage. Additionally, when the dispenser wireless transceiver is positioned such that upon placement of a compatible container in a location to properly receive the beverage from the valve, the dispenser wireless transceiver may be aligned with the container wireless transceiver of the beverage container. In yet another embodiment, when the beverage container is placed under the valve, the dispenser wireless transceiver may transmit a first electronic signal to the beverage container and the container wireless transceiver may transmit a second electronic signal to the dispenser wireless transceiver to confirm proper placement under the valve and to confirm that the beverage container is a compatible container to receive the beverage from the valve, and wherein the valve subsequently dispenses the beverage into the beverage container.

Further aspects of the invention are related to a beverage container configured to communicate with a beverage dispenser that includes a dispenser wireless transceiver. The beverage container may include a sidewall disposed around a central bottom, wherein the bottom is distal to an opening for receiving a beverage and a container wireless transceiver affixed to the container, with the container wireless transceiver configured to communicate with the dispenser wireless transceiver. In one embodiment, the container wireless transceiver may be affixed to the bottom of the container. In other embodiments, the container wireless transceiver may be affixed to the sidewall of the container. Yet in other embodiments, the container wireless transceiver may be located in an impermeable layer between the sidewall and the bottom of the container, wherein the impermeable layer is not in fluid communication with the location where the beverage would be received in the opening. Additionally, the container wireless transceiver may be configured to transmit an electronic signal indicative that the beverage container is validated to receive a beverage and whether the beverage container is properly located to receive the beverage from the valve of the drink dispenser.

Further aspects of the invention are related to a beverage dispenser configured to communicate with a beverage container that includes a wireless transceiver. The beverage dispenser may include a housing, a valve extending from the housing configured to dispense the beverage into the container located below the valve, and a dispenser wireless transceiver located in close proximity to the beverage dispenser configured to communicate with the container wireless transceiver on the beverage container. The beverage dispenser may further include a valve lever that extends from the housing, wherein in some embodiments the dispenser wireless transceiver may be located on the valve lever. In other embodiments, the valve lever may include a lever backing that extends from the housing, wherein the dispenser wireless transceiver is located on the lever backing. The dispenser

3

wireless transceiver may be configured to receive a return signal from a compatible container indicative that the beverage container is validated to receive the beverage from the beverage dispenser and whether the beverage container is properly located to receive the beverage. Additionally, when the dispenser wireless transceiver is positioned such that upon placement of a compatible container in a location to properly receive the beverage from the valve, the dispenser wireless transceiver may be aligned with the container wireless transceiver of the beverage container. In yet another embodiment, when the beverage container is placed under the valve, the dispenser wireless transceiver may transmit a first electronic signal to the beverage container and the container wireless transceiver may transmit a second electronic signal to the dispenser wireless transceiver to confirm proper placement under the valve and to confirm that the beverage container is a compatible container to receive the beverage from the valve, and wherein the valve subsequently dispenses the beverage into the beverage container.

Further aspects of the invention are related to a method for dispensing fluids for example with the container and beverage dispenser or beverage dispensing system as described above. The method may include the steps of: 1) sensing a beverage container in close proximity to a beverage dispenser; 2) transmitting a first electronic signal to the beverage container from a dispenser wireless transceiver located in close proximity to the beverage dispenser; 3) transmitting a second electronic signal to the dispenser wireless transceiver from a container wireless transceiver associated with the container; and 4) dispensing the fluid from the beverage dispenser to the beverage container. Additionally, the transmission of the first electronic signal and the second electronic signal may confirm the proper placement of the beverage container under the beverage dispenser and may confirm that the beverage container is a compatible container to receive a fluid from the beverage dispenser.

These and other features and advantages of the present invention will become apparent from the description of the preferred embodiments, with reference to the accompanying drawing figures.

BRIEF DESCRIPTION OF THE DRAWINGS

The present disclosure is illustrated by way of example and not limited in the accompanying figures in which like reference numerals indicate similar elements and in which:

FIG. 1 illustrates a perspective view of an exemplary beverage dispensing system in accordance with aspects of the invention;

FIG. 2 illustrates a perspective view of an exemplary beverage container that may be used with the beverage dispensing system from FIG. 1 in accordance with aspects of the invention;

FIG. 3A illustrates a front perspective view of an exemplary beverage dispenser that may be used with the beverage dispensing system from FIG. 1 in accordance with aspects of the invention; and

FIGS. 3B and 3C illustrate rear perspective views of the beverage dispenser from FIG. 3A in accordance with aspects of the invention.

The reader is advised that the attached drawings are not necessarily drawn to scale.

DETAILED DESCRIPTION OF THE INVENTION

In the following description of various examples of the invention, reference is made to the accompanying drawings,

4

which form a part hereof, and in which are shown by way of illustration various example structures, systems, and steps in which aspects of the invention may be practiced. It is to be understood that other specific arrangements of parts, structures, example devices, systems, and steps may be utilized and structural and functional modifications may be made without departing from the scope of the present invention. Also, while the terms “top,” “bottom,” “front,” “back,” “side,” and the like may be used in this specification to describe various example features and elements of the invention, these terms are used herein as a matter of convenience, e.g., based on the example orientations shown in the figures. Nothing in this specification should be construed as requiring a specific three dimensional orientation of structures in order to fall within the scope of this invention.

An exemplary beverage dispensing system may comprise one or more components shown in FIGS. 1 through 3C. As illustrated in FIGS. 1 through 3C, the beverage dispensing system 10 may comprise a container 100 and a beverage dispenser 200. As is shown in FIG. 1, the beverage dispensing system may include one or more beverage dispensers 200. Additionally, as shown in FIG. 1, the beverage dispensing system may include beverage dispensers in accordance with the present invention and traditional beverage dispensers utilized in the prior art, represented by the box labeled “PRIOR ART” in FIG. 1.

As illustrated in FIG. 2, aspects of the invention relate to novel beverage containers that can be utilized with a beverage dispenser 200 in accordance with this invention, such as container 100. Exemplary container 100 may contain a side-wall 102 disposed around a central bottom 104, wherein the bottom 104 is distal to an opening (not shown) for receiving a beverage. While the exemplary container 100 is shown as an open-faced cup, those skilled in the art will readily appreciate that other containers that are configured to hold a beverage, such as a bottle, can, bowl, or any structure that may receive a fluid, may be utilized in accordance with one or more embodiments of the invention.

Additionally, the container 100 may be made of any materials known and used in the art. The container 100 may be made the materials, such as: plastic, Styrofoam™, paper, or metal in accordance with aspects of this invention. Additionally, the container 100 may be any size as known and used in the art without departing from this invention.

In accordance with one embodiment, the container 100 comprises a wireless transceiver 106. The wireless transceiver 106 may be configured to utilize one or more forms of wireless technology, including but not limited to: radio frequency identification (RFID), electronic article surveillance (EAS), Bluetooth, cellular, and/or any transmissions in accordance with IEEE 802.xx. Indeed, any component(s) configured to transmit and/or receive wireless signals is within the scope of this disclosure. In accordance with aspects of this invention, the wireless transceiver 106 may be in the form of RFID, similar to examples such as automated automobile toll collection or security access cards. Additionally, the wireless transceiver 106 may be in the form of an EAS system. EAS systems are generally used in a retail setting for security and to help protect against shoplifting.

RFID systems generally may include one or more RFID tags that may be inductively-coupled, capacitively-coupled, active, semi-passive, and passive. In general, each RFID tag works by first, storing data within an RFID tag's microchip. The RFID tag may include an antenna that receives electromagnetic energy from an RFID reader's antenna. Using power from the RFID tag's internal battery or power harvested from the reader's electromagnetic field, the tag may

5

then send radio waves back to the reader. The reader may then receive the RFID tag's radio waves and interpret the frequencies as meaningful data.

EAS systems may include technologies such as radio frequency (RF) systems, electromagnetic systems, acousto-magnetic systems, or microwave systems. RF systems generally work with an RF tag or label attached to a product, with the RF tag being basically a miniature, disposable electronic circuit and antenna. The RF tag or label may respond to a specific frequency emitted by a transmitter antenna. For electromagnetic systems, a magnetic, iron-containing strip may be attached to the product. This electromagnetic strip can be activated or deactivated using a highly intense magnetic field. The electromagnetic strip may respond to electromagnetic field transmitted from a transmitter antenna. For acousto-magnetic systems, a transmitter sends a radio-frequency signal in pulses, which in turn may energize a tag within the transmitted zone. When the pulse ends, the tag responds, emitting a single frequency signal like a tuning fork. While the transmitter is off between pulses, the tag signal is detected by the receiver and is checked to ensure it is the correct frequency. If all these criteria are met, the tag is signaled as correct (or alarmed in the example of a security system).

These wireless systems are different systems known and used in the art at the present time, however, any component(s) configured to transmit and/or receive wireless signals is within the scope of this invention.

As shown in FIG. 2, wireless transceiver 106 may be affixed or molded to the bottom 104 of the beverage container 100. In other embodiments, however, the wireless transceiver 106 may be located on, affixed to, or otherwise associated with a sidewall 102 of the container 100. Yet in further embodiments, the wireless transceiver 106 may be located within a secondary compartment of container 100. For example, an impermeable layer or structure may be placed between the sidewall 102 and/or the bottom 104 of the container 100 to create an internal compartment that is not in fluid communication with the location where a beverage would be received in the opening (not shown). As discussed in more detail below, the wireless transceiver 106 may be configured to transmit information to a beverage dispenser, such as a dispenser 200 shown in FIGS. 3A through 3C.

An exemplary beverage dispenser 200 is shown in FIGS. 3A through 3C. The term "beverage" has been used to readily convey exemplary embodiments to reader, however, those skilled in the art will readily appreciate that any liquid, gel, or similar product, including for example, concentrated syrup, is within the scope of the invention. Therefore, while the below embodiments are explained in relation to a ready-made beverage, readers are advised that the dispensing of any liquid, gel, or similar product is within the scope of the invention. The exemplary beverage dispenser 200 may generally resemble a traditional fountain-drink dispenser and may comprise a valve 202, a housing 204, and a valve lever 212.

As illustrated in FIGS. 3A through 3C, the housing 204 may include a front housing area 206 and a rear housing area 207. The front housing area 206 may include a push-button 208. The push-button 208 may include a logo of the beverage to be dispensed from the beverage dispenser 200. Additionally, the push-button 208 may illuminate at different times, such as when the push-button 208 is pushed, when the beverage dispenser 200 is ready, or when the beverage dispenser 200 is communicating with a container 100. Additionally, the push-button 208 may illuminate and blink at varying times or varying frequencies to signal events or activities. In accordance with aspects of this invention, the push-button 208 may only be a button, that may not be pushed at all. Pressing the

6

push-button 208 may control the flow of the beverage from the valve 202 to the container 100. Additionally, in accordance with other aspects of this invention, the housing 204 may include a lever actuator that may actuate the valve 202 and dispense the beverage from the valve 202 to the container 100.

In addition to the push-button 208, the front housing 206 may also include electronics 210. The electronics 210 may be self-contained within the front housing 206 as is illustrated specifically in FIG. 3C. The electronics 210 may be in the form of a circuit board or other similar control electronics capable of controlling the functionality and operability of the beverage dispenser 200. The electronics 210 may also help facilitate communication between the container 100 and the beverage dispenser 200.

The rear housing 207 may include a set of connections 220 to the beverage dispensing system 10. As illustrated in FIGS. 3B and 3C, these connections 220 may include tubing or similar-type connection ends configured to attach to the tubing or connection of the beverage dispensing system 10. The connections 220 may also be capable of connecting directly to individual beverage lines, such as when the beverage dispenser 200 is not used as part of a beverage dispensing system 10.

As illustrated in FIGS. 3A through 3C, the beverage dispenser may also include a valve 202. The valve 202 may protrude or extend from the housing 204 as is shown in FIG. 3A. While the term "valve" is used throughout this disclosure, those skilled in the art will readily appreciate that any outlet configured to dispense a liquid is within the scope of invention. The valve 202 may be configured to dispense a beverage into a compatible container 100. Additionally, the valve 202 may include a relay or electromechanical switch that turns the valve on or off (or enabled or disabled) based on the presence of a compatible container 100.

Additionally, as illustrated in FIGS. 3A through 3C, the beverage dispenser may include a valve lever 212. The valve lever 212 may protrude or extend from the housing 204 as shown in FIG. 3A. The valve lever 212 may be of any of various shapes and sizes without departing from this invention. As discussed in more detail below, the use of the valve lever 212 may be further supplanted or replaced with a wireless transceiver, such as a wireless transceiver 216 located on the beverage dispenser 200. The valve lever 212 may also include a lever backing 218. The lever backing 218 may extend from the housing 204, and more specifically, from the rear housing 207. The lever backing 218 may include the wireless transceiver 216 as illustrated in FIG. 3A. For example, the wireless transceiver 216 may be located on the lower portion of the lever backing 218. Additionally, the beverage dispenser 200 may not include the lever backing 218, and in this instance, the transceiver 216 may be located on the valve lever 212. In another embodiment in accordance with this invention, the beverage dispenser 200 does not include a valve lever 212 and only includes the lever backing 218, wherein the transceiver 216 may be located on the lever backing 218.

As illustrated in FIGS. 3A through 3C, the beverage dispenser 200 and more specifically, the valve 202, may dispense a beverage into a compatible container, such as the container 100 as illustrated in FIG. 2. Construction of exemplary containers has been described above in relation to FIG. 2, and is also known in the art. As discussed below, however, in certain embodiments the presence and/or orientation of a wireless transceiver 106 within, affixed to, imbedded or otherwise

7

associated with container **100** may be determinative of whether a beverage receptacle may be considered a compatible container **100**.

In certain embodiments, valve **202** may be in operative communication with a valve lever **212** which may be mechanical, electrical, or electro-mechanical. In one embodiment having valve lever **212**, pressure may be placed upon the valve lever **212** (for example, along the direction of arrow **214**), as container **100** is placed under the valve **202**. Pressure upon the valve lever **212** may transmit a signal (electrical or mechanical) indicating the presence of a container, such as container **100**. In one embodiment where transceiver **216** is located on the lower portion of the lever backing **218**, a container **100** configured for use with dispenser **200** may include the wireless transceiver **106** located on or near its bottom **104**, such that the wireless transceiver **216** of the beverage dispenser **200** is aligned with wireless transceiver **106** of the container **100**.

In one embodiment, the wireless transceiver **216** of the dispenser **200** is configured to transmit an electronic signal. The transmission of the electronic signal may be set to a continuous loop, such that the signal is continually transmitted. Yet in other embodiments, the transmission of the electronic signal may be dependant on one or more conditions, such as determined or influenced by a timer, a motion sensor (which may external to the dispenser **200**) or any other hardware or software in communication with dispenser **200**. As discussed above in relation to the embodiment shown in FIG. **3A**, the wireless transceiver **216** may be located in the lever backing **218** of the valve lever **212**, such that a consumer may press the container **100** against it to dispense the beverage from valve **202**. In one embodiment, the electronic signal transmitted from wireless transceiver **216** is received by wireless transceiver **106** on container **100** when container **100** is correctly placed to receive a beverage from the valve **202**. In this regard, one or both of the wireless transceivers **106**, **216** are configured to transmit a signal that may only be received by the other when each are within a threshold distance from each other. Yet in other embodiments, the signal transmitted from one of the transceivers **106**, **216** may be received by the other transceiver **106**, **216** at a distance that is further than when the container **100** is properly placed to receive a beverage from the valve **202**, however, the dispenser **200** is configured such that a threshold signal strength or proximity measurement is required for the valve **202** to dispense the beverage, wherein the threshold strength or proximity measurement is met only when the container **204** is properly located to receive a beverage from valve **202**.

In one embodiment, upon receiving the electronic signal from the wireless transceiver **216**, the wireless transceiver **106** of the container **100** may transmit a return signal indicating that the container is located in a proper configuration to receive the beverage, such as the placement of the container **100** in relation to valve **202** shown in FIG. **3A**. In this regard, the beverage is only dispensed when the container **100** having a wireless transceiver **106** transmitting a valid electronic return signal is correctly placed to receive the beverage.

In one embodiment, the wireless transceiver **106** is configured to transmit information to enable a beverage to be dispensed from a specific valve **202**. Yet in other embodiments, the wireless transceiver **106** is configured to enable the dispensing of a beverage from several different valves. In one such embodiment, at least one valve dispenses a fluid that is different than the fluid dispensed from at least one other valve. In another embodiment, the wireless transceivers **106**, **216** do not require complex circuitry that requires information to be rewritten with additional information, such as the

8

amount of beverage dispensed, quantity of times the container has been utilized at one or more dispensers **200**, or other information. Yet in other embodiments, information, including one or more of the parameters above (and/or other parameters) may be transmitted. Furthermore, in certain embodiments, one or more of the electronic signals transmitted from the wireless transceiver(s) **106**, **216** does not include information regarding the purchaser or user of container **100**. Yet in other embodiments, such information regarding the purchaser or user of container **100** may be utilized.

In one embodiment, one or more of the electronic signals to be transmitted from container **100** to the transceiver **216** is determined and configured before a consumer purchases the cup. Therefore, in certain embodiments, this would reduce the complexity and time required for transactions related to selling or otherwise providing container **100** to a consumer.

As those skilled in the art will readily appreciate in view of this disclosure, either wireless transceiver **106**, **216** may be located at other locations associated with the beverage dispenser **200** and the container **100**.

The advantages and benefits of a beverage dispensing system in accordance with this invention may be readily apparent to those of skill in the art. Specifically, one advantage of the beverage dispensing system **10** may be controlled access to premium beverages at a beverage dispensing system. Because of the transmissions between the transceiver **106** on the container **100** and the transceiver **216** on the beverage dispenser **200**, the beverage dispenser system **10** may provide controlled access to premium beverages. Another advantage for the beverage dispensing system **10** may be that the RFID/EAS equipped valves and wireless systems are generally more difficult to bypass than systems that utilize mechanical or contact/switch systems as used in the prior art. Additionally, the beverage dispensing system **10** does not require physical contact between the container **100** and the valve **202** to activate the beverage dispenser system **10**, thereby making the beverage dispensing system **10** of the present invention easier to use and generally more sanitary.

CONCLUSION

The present invention is disclosed above and in the accompanying drawings with reference to a variety of examples. The purpose served by the disclosure, however, is to provide an example of the various features and concepts related to the invention, not to limit the scope of the invention. One skilled in the relevant art will recognize that numerous variations and modifications may be made to the aspects described above without departing from the scope of the present invention, as defined by the appended claims.

We claim:

1. A method for dispensing fluids, the method comprising the steps of:
 - sensing a beverage container in close proximity to a beverage dispenser, wherein the beverage dispenser further includes a housing with a push-button and a valve extending from the housing configured to dispense a fluid into the beverage container located below the valve, wherein pushing the push-button controls a flow of the fluid from the valve to the beverage container;
 - transmitting a first electronic signal to the beverage container from a dispenser wireless transceiver located in close proximity to the beverage dispenser;
 - transmitting a second electronic signal to the dispenser wireless transceiver from a container wireless transceiver associated with the container; and

9

dispensing the fluid from the beverage dispenser to the beverage container,

wherein the first electronic signal and the second electronic signal meet a threshold signal strength that is required for the valve to dispense the fluid, and wherein the threshold signal strength is met only when the first electronic signal and the second electronic signal confirm proper placement of the beverage container under the beverage dispenser and confirm that the beverage container is a compatible container to receive the fluid from the beverage dispenser, and further wherein the push-button illuminates when the beverage dispenser is communicating with the beverage container.

2. The method according to claim 1, wherein the dispenser wireless transceiver is positioned such that upon placement of a compatible container in a location to properly receive the fluid from the valve, the dispenser wireless receiver is aligned with the container wireless transceiver.

3. The method according to claim 1, wherein the beverage container further comprises a sidewall disposed around a central bottom, wherein the bottom is distal to an opening for receiving a beverage.

4. The method according to claim 3, wherein the container wireless transceiver is affixed to the bottom of the beverage container.

5. The method according to claim 3, wherein the container wireless transceiver is affixed to the sidewall of the beverage container.

6. The method according to claim 3, wherein the container wireless transceiver is located in an impermeable layer between the sidewall and the bottom of the beverage container, wherein the impermeable layer is not in fluid communication with the location where the fluid would be received in the opening.

7. The method according to claim 1, wherein the valve includes a relay or electromechanical switch that turns the valve on or off based on the communication between the container wireless transceiver and the dispenser wireless transceiver.

8. The method according to claim 1, wherein the first electronic signal is continually transmitted from the dispenser wireless transceiver.

9. The method according to claim 1, wherein the dispenser wireless transceiver and the container wireless transceiver transfer information that can be rewritten.

10. A method for dispensing beverage into a beverage container, the method comprising the steps of:

sensing a beverage container in close proximity to a beverage dispenser,

wherein the beverage container includes a sidewall disposed around a central bottom, wherein the bottom is distal to an opening for receiving a beverage, and

wherein the beverage dispenser further includes a housing with a push-button and a valve extending from the housing configured to dispense the beverage into the beverage container located below the valve, wherein pushing the push-button controls a flow of the beverage from the valve to the beverage container;

transmitting a first electronic signal to the beverage container from a dispenser wireless transceiver located in close proximity to the beverage dispenser;

transmitting a second electronic signal to the dispenser wireless transceiver from a container wireless transceiver associated with the beverage container; and

dispensing the beverage from the beverage dispenser to the beverage container,

10

wherein the transmission of the first electronic signal and the second electronic signal confirm proper placement of the beverage container under the beverage dispenser and confirm that the beverage container is a compatible container to receive the beverage from the beverage dispenser, and further wherein the push-button illuminates when the beverage dispenser is communicating with the beverage container.

11. The method according to claim 10, wherein the valve includes a relay or electromechanical switch that turns the valve on or off based on the communication between the dispenser wireless transceiver and the wireless transceiver on the container.

12. The method according to claim 10, wherein the beverage dispenser further includes a valve lever that extends from the housing.

13. The method according to claim 12, wherein the dispenser wireless transceiver is located on the valve lever.

14. The method according to claim 12, wherein the valve lever includes a lever backing that extends from the housing, wherein the dispenser wireless transceiver is located on the lever backing.

15. The method according to claim 10, further including the step of: receiving by the dispenser wireless transceiver a return electronic signal from a compatible container indicative that the beverage container is validated to receive the beverage from the beverage dispenser.

16. The method according to claim 10, wherein the dispenser wireless transceiver transfers and receives information that can be rewritten onto the dispenser wireless transceiver.

17. A method for dispensing a beverage into a beverage container, the method comprising the steps of:

sensing a beverage container in close proximity to a beverage dispenser,

wherein the beverage dispenser further includes a housing with a push-button and a valve extending from the housing configured to dispense a beverage into the beverage container located below the valve;

when the beverage container is placed under the valve, transmitting a first electronic signal to the beverage container from a dispenser wireless transceiver located in close proximity to the beverage dispenser;

when the beverage container is placed under the valve, transmitting a second electronic signal to the dispenser wireless transceiver from a container wireless transceiver associated with the container; and

dispensing the beverage from the beverage dispenser to the beverage container,

wherein the first electronic signal and the second electronic signal confirm proper placement under the valve and

confirm that the beverage container is a compatible container to receive the beverage from the valve, and wherein, upon a push-button or a lever actuation, the valve subsequently dispenses the beverage into the beverage container, wherein the first electronic signal and the second electronic signal meet a threshold signal strength that is required for the valve to dispense the beverage, and further wherein the threshold signal strength is met only when the beverage container is properly located to receive the beverage from the valve,

and further wherein the push-button illuminates when the beverage dispenser is communicating with the beverage container.

18. The method according to claim 17, wherein the beverage dispenser further includes a valve lever that extends from the housing and the dispenser wireless transceiver is located on the valve lever.

11

19. The method according to claim 17, wherein the dispenser wireless transceiver is positioned such that upon placement of a compatible container in a location to properly receive the beverage from the valve, the dispenser wireless receiver is aligned with the container wireless transceiver. 5

20. The method according to claim 17, wherein the beverage container further comprises a sidewall disposed around a central bottom, wherein the bottom is distal to an opening for receiving a beverage and the container wireless transceiver is located in an impermeable layer between the sidewall and the 10 bottom of the beverage container, wherein the impermeable layer is not in fluid communication with the location where the beverage would be received in the opening.
